

Two kinds of position, one rule: draw from the model until the keyed response accepts, at most R times.

two-sided

Steerable carrier

$S > 0.5$: both response signs plausible

accepted: still a sample from the model's own conditional

counted by the detector; the only positions that can pay quality, less than one bit each

one-sided

Key-opposed position

target side holds $\sim$ no mass

exhausted: one unconditional draw, the natural sample

zero quality cost by construction; excluded by the detector's gate

Verification

from the finished text alone, with no access to the trajectory or the draw sequence

the model fills in any order

finished text

[M] model [M] in [M] order

re-masked under the key
